

Heavily based on material from:  
Murach's MySQL (3rd Edition), by Joel Murach

# Normalization

The process of organizing the columns (attributes) and tables (relations) of a relational database to **minimize data redundancy**.

Normalization involves **decomposing** a table into less redundant (and smaller) tables without losing information; defining foreign keys in the old table referencing the primary keys of the new ones.

The objective is to isolate data so that additions, deletions, and modifications of an attribute can be made in just one table and then propagated through the rest of the database using the defined foreign keys.

What is  
**NORMAL**?

# Normalization

There are 10 normal forms, but *typically* only 3 are applied.

Though normalization reduces redundancy, it can cause storage and maintenance problems.

I found references for **10** normal forms (not including “unnormalized form”).

[https://en.wikipedia.org/wiki/Database\\_normalization](https://en.wikipedia.org/wiki/Database_normalization)

## The first three normal forms

| Normal form         | Description                                                                                                                             |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>First (1NF)</b>  | The value stored at the intersection of each row and column must be a scalar value, and a table must not contain any repeating columns. |
| <b>Second (2NF)</b> | Every non-key column must depend on the entire primary key.                                                                             |
| <b>Third (3NF)</b>  | Every non-key column must depend only on the primary key.                                                                               |

### Note

- Most database designers stop at the third normal form.

## The next four normal forms

| Normal form                     | Description                                                                                                                                  |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Boyce-Codd (BCNF)</b>        | A non-key column can't be dependent on another non-key column.                                                                               |
| <b>Fourth (4NF)</b>             | A table must not have more than one <i>multivalued dependency</i> , where the primary key has a one-to-many relationship to non-key columns. |
| <b>Fifth (5NF)</b>              | The data structure is split into smaller and smaller tables until all redundancy has been eliminated.                                        |
| <b>Domain-key (DKNF)</b>        | <b>Every constraint on the relationship is dependent only on key constraints</b>                                                             |
| <b>Sixth(6NF)</b><br>is the set | <b><i>domain</i> constraints, where a domain</b><br><br>of allowable values for a column.                                                    |

## Two tables that need to be normalized

### A table that contains repeating columns

|   | vendor_name        | invoice_number | item_description_1 | item_description_2 | item_description_3 |
|---|--------------------|----------------|--------------------|--------------------|--------------------|
| ▶ | Cahners Publishing | 112897         | VB ad              | SQL ad             | Library directory  |
|   | Zylka Design       | 97/552         | Catalogs           | SQL flyer          | NULL               |
|   | Zylka Design       | 97/553B        | Card revision      | NULL               | NULL               |

A table that contains a column for each invoice item. Ick!

### A table that contains redundant data

|   | vendor_name        | invoice_number | item_description  |
|---|--------------------|----------------|-------------------|
| ▶ | Cahners Publishing | 112897         | VB ad             |
|   | Cahners Publishing | 112897         | SQL ad            |
|   | Cahners Publishing | 112897         | Library directory |
|   | Zylka Design       | 97/522         | Catalogs          |
|   | Zylka Design       | 97/522         | SQL flyer         |
|   | Zylka Design       | 97/533B        | Card revision     |

A table that contains a description for each invoice item. More ick!

**REDUNDANCY**

## Terms

- Normalization
- Data redundancy
- Unnormalized data structure
- Normalized data structure
- Normal forms

# Benefits of Normalization

1. The process of organizing the columns (attributes) and tables (relations) of a relational database to **minimize data redundancy**.
2. More tables, and **each table can have an PK index**, the database has more PK indexes. That makes **data retrieval more efficient**.
3. Each table contains information about a single entity, and **each index has fewer columns** (usually one) and fewer rows. That makes data retrieval and **insert, update, and delete operations more efficient**.
4. Each **table has fewer indexes**, which makes **insert, update, and delete operations more efficient**.
5. **Simplified maintenance and reduced storage**, due to reduced data redundancy, i.e. efficiency.

## Unnormalized invoice data

### The invoice data with a column that contains repeating values

|   | vendor_name        | invoice_number | item_description                 |
|---|--------------------|----------------|----------------------------------|
| ▶ | Cahners Publishing | 112897         | VB ad, SQL ad, Library directory |
|   | Zylka Design       | 97/522         | Catalogs, SQL Flyer              |
|   | Zylka Design       | 97/533B        | Card revision                    |

Notice the comma separated values in the column.

Application developers LOVE to do this kind of thing

### The invoice data with repeating columns

|   | vendor_name        | invoice_number | item_description_1 | item_description_2 | item_description_3 |
|---|--------------------|----------------|--------------------|--------------------|--------------------|
| ▶ | Cahners Publishing | 112897         | VB ad              | SQL ad             | Library directory  |
|   | Zylka Design       | 97/552         | Catalogs           | SQL flyer          | NULL               |
|   | Zylka Design       | 97/553B        | Card revision      | NULL               | NULL               |

What happens when we have an order with 4 items?

## The invoice data in first normal form with keys added

Before

|   | invoice_id | vendor_name        | invoice_number | invoice_sequence | item_description  |
|---|------------|--------------------|----------------|------------------|-------------------|
| ▶ | 1          | Cahners Publishing | 112897         | 1                | VB ad             |
|   | 1          | Cahners Publishing | 112897         | 2                | SQL ad            |
|   | 1          | Cahners Publishing | 112897         | 3                | Library directory |
|   | 2          | Zylka Design       | 97/522         | 1                | Catalogs          |
|   | 2          | Zylka Design       | 97/522         | 2                | SQL flyer         |
|   | 3          | Zylka Design       | 97/533B        | 1                | Card revision     |

The keys added to order the items in the invoice.

For a table to be in second normal form, **every non-key column must depend on the entire primary key**. If a column does not depend on the entire primary key, it indicates that the table contains data for more than one entity.

|   | vendor_name        | invoice_number | item_description  |
|---|--------------------|----------------|-------------------|
| ▶ | Cahners Publishing | 112897         | VB ad             |
|   | Cahners Publishing | 112897         | SQL ad            |
|   | Cahners Publishing | 112897         | Library directory |
|   | Zylka Design       | 97/522         | Catalogs          |
|   | Zylka Design       | 97/522         | SQL flyer         |
|   | Zylka Design       | 97/533B        | Card revision     |

The duplicate data representing the vendor name has been removed.

|   | InvoiceNumber | VendorName         | InvoiceID |
|---|---------------|--------------------|-----------|
| 1 | 112897        | Cahners Publishing | 1         |
| 2 | 97/522        | Zylka Design       | 2         |
| 3 | 97/533B       | Zylka Design       | 3         |

A new table representing the **invoice\_line\_items** has been created.

This allows the vendor name to only occur once, in the invoices table.

|   | InvoiceID | InvoiceSequence | ItemDescription   |
|---|-----------|-----------------|-------------------|
| 1 | 1         | 1               | VB ad             |
| 2 | 1         | 2               | SQL ad            |
| 3 | 1         | 3               | Library directory |
| 4 | 2         | 1               | Catalogs          |
| 5 | 2         | 2               | SQL flyer         |
| 6 | 3         | 1               | Card revision     |

## The A/P system in second normal form

Additional columns are shown here.

## Questions about the structure

**NO**

1. Does the vendor information (Vendor\_Name, Vendor\_Address, etc.) depend only on the Invoice\_ID column?

**NO**

2. Does the Terms column depend only on the Invoice\_ID column?

**NO**

3. Does the Account\_No column depend only on the Invoice\_ID column?

**YES!**

4. Can the Invoice\_Due\_Date and Invoice\_Line\_Item\_Amount columns be derived from other data?

| invoices                  |                  |
|---------------------------|------------------|
| invoice_id                |                  |
| vendor_name               | invoice_date     |
| vendor_address            | invoice_total    |
| vendor_city               | payment_total    |
| vendor_state              | credit_total     |
| vendor_zip_code           | terms            |
| vendor_phone              | invoice_due_date |
| vendor_contact_first_name | payment_date     |
| vendor_contact_last_name  | account_no       |
| invoice_number            |                  |

Before

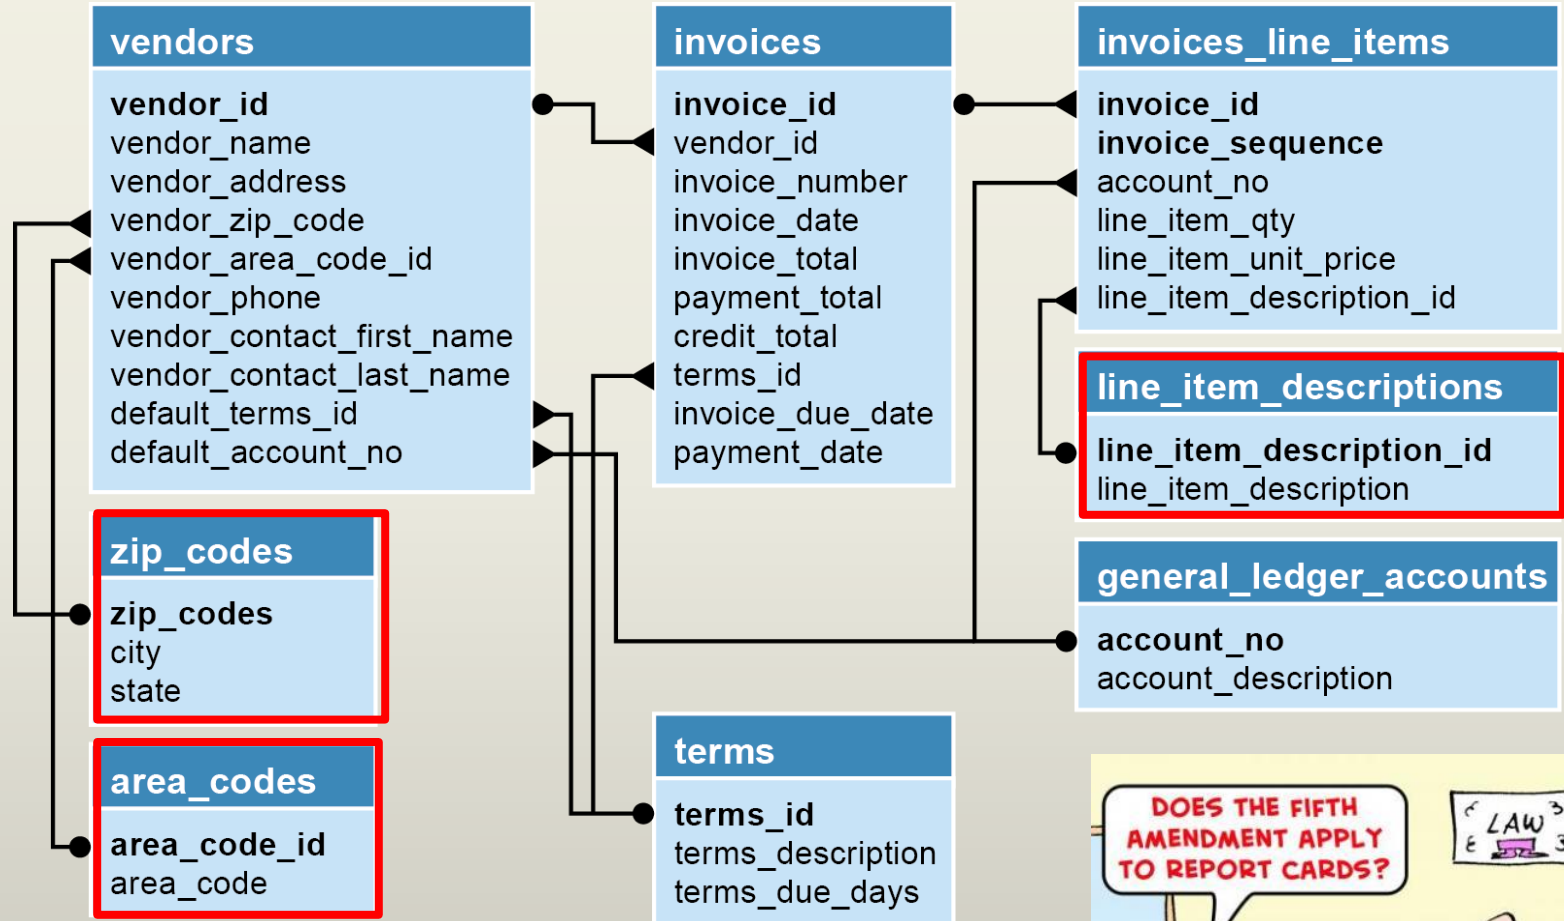

| invoice_line_items    |  |
|-----------------------|--|
| invoice_id            |  |
| invoice_sequence      |  |
| account_no            |  |
| line_item_description |  |
| line_item_quantity    |  |
| line_item_unit_price  |  |
| line_item_amount      |  |

## The accounts payable system in third normal form

We created the Vendors, Terms, and GLAccounts tables and moved duplicative columns into the new tables.

# The accounts payable system in fifth normal form

If we wanted to go to fifth-normal form, we'd need to add 3 new tables.

Jesse Chaney

# Do we always normalize?

An objective of **normalization** is to reduce redundant data stored in the database.

In a **transactional database**, normalization helps us with data consistency and correctness.

What are the conditions that may cause us to **denormalize** a database?

NORMAL  
IS  
BORING

## When to denormalize

1. When a column from a joined table is used **repeatedly** in search criteria.
2. If a table is **updated infrequently**.
3. Include columns with derived values when those values are used frequently in search conditions.

**Denormalization** is a strategy used on a previously-normalized database to **increase performance**.

The idea behind it is to add redundant data where we think it will help us the most.

Other reasons to denormalize?

Highly normalized databases can often require many-Many-**MANY** joins before you can get out any useful data. Denormalization can reduce the length of the SQL statements.

**Denormalization is often done on reporting databases.**
